CREATIO AI CONSULTANT — SOLUTION DESIGN SAMPLE

# A workflow for reviewing public records

Prepared by Tim Sullivan | August 11, 2026 | Conceptual Creatio mapping; no Creatio deployment is claimed.

**OBJECTIVE:** Reduce the manual effort required to assemble address-based public records while preserving exact sources, unresolved fields, and human control over consequential output.

## Current process

A property or community review can require separate federal, state, county, regional, and municipal searches. Sources use different address formats, update schedules, query interfaces, and meanings. An unavailable record cannot safely be converted into “none exists,” and a screening result cannot become a legal, engineering, insurance, environmental, lending, or regulatory determination.

### Stakeholders and decisions

- Municipal or regional staff: locate records, create an inventory, and route unresolved items.
- Environmental and engineering consultants: assemble evidence before fieldwork or professional review.
- Property professionals: identify which official records require attention before a transaction or project.
- Review owner: decide whether the evidence is sufficient to release, escalate, or leave unresolved.

### Use-case priority

| Use case | Business value | Feasibility / risk | Current state |
|---|---|---|---|
| One-address, source-cited review | Reduce repeated portal searches | Requires records and scope checks | Varies by location |
| Unresolved-item queue | Show missing records and follow-up tasks | Requires owners and due dates | Implemented as product state |
| Community address filtering | Compare records across an area | Feasible where a denominator and layer are available | Implemented in bounded workflows |
| Multi-town coalition view | Compare jurisdictions | Requires generalized jurisdiction and denominator model | Roadmap; not generalized |

Priority rule: automate repetitive, evidence-bounded steps first; retain human review where an error changes an external decision.

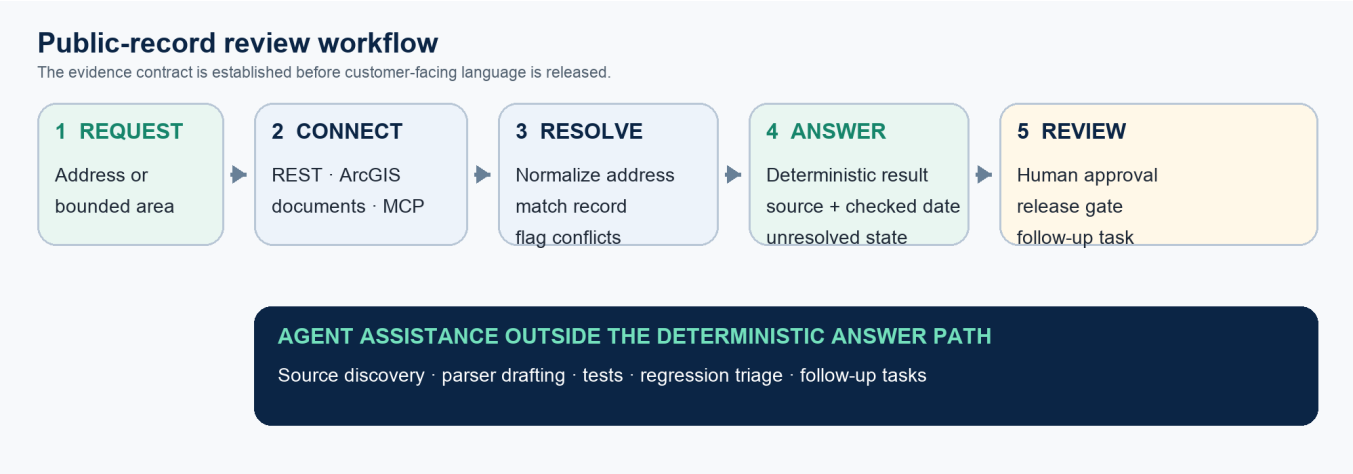

### Proposed discovery questions

1. Which decision is the review supporting, and which records are authoritative for that decision?
2. What is the full denominator: one address, every parcel in one jurisdiction, or a multi-town region?
3. What output requires human approval, and who owns unresolved items?
4. Which measures establish value: cycle time, exact-source coverage, error rate, unresolved closure, or cost per completed review?

SOLUTION ARCHITECTURE

# Keep record checks separate from agent assistance

The model is used where judgment and synthesis help. Deterministic services retain responsibility for address matching and compliance-adjacent result fields.

## Proposed Creatio implementation

- Record model: a case, property, or portfolio record stores the request, jurisdiction, review stage, returned findings, sources, owners, approvals, and unresolved work.
- Business Studio: orchestrates intake, connector calls, review tasks, approval steps, service levels, and exception paths.
- AI Studio: agents triage candidate sources, summarize conflicts, prepare follow-up tasks, and draft review notes inside a constrained schema.
- Integration layer: REST and MCP tools separate retrieval from verification; credentials and permissions remain outside model context.
- Release control: a human approval step controls external delivery whenever a result is incomplete, conflicting, or consequential.
- Operations: dashboards report cycle time, exact-source coverage, unresolved aging, exception rate, and cost per completed review.

## Guardrail contract

| Control | Enforcement | Failure behavior |
|---|---|---|
| Evidence | Official source, URL, checked date, scope and adapter version | Hold result or mark unresolved |
| Entity resolution | Normalized address plus positive controls on known records | No match is not treated as no record |
| Language | Allowed statements derived from source-support contract | Use “Not confirmed”; prohibit determination language |
| Permissions | Role-based access; secrets remain outside prompts | Deny tool call and create review task |
| Release | Computed, reviewed, customer-visible and public states remain separate | No external release without required approval |
| Monitoring | Golden-set regression checks and exception sampling | Rollback or quarantine affected source lane |

**DESIGN DECISION:** The customer-facing answer path remains reproducible. Agents can propose, summarize and route work; they do not convert absent evidence into a consequential property determination.

PILOT AND MEASUREMENT

# Test one workflow before expanding

Start with one jurisdiction, one source family, one review owner, and a golden set of known records.

## Four-stage pilot

**1. Discovery** Map current steps, decisions, systems, owners, permissions, volumes, baseline time and failure modes.

**2. Prototype** Configure the record model and one workflow; connect one source family; define agent tools, approvals and the golden test set.

**3. Controlled pilot** Run live work with human review; record exceptions, unresolved reasons, review time and user feedback.

**4. Scale decision** Expand only if source accuracy, workflow adoption, cycle-time reduction and exception handling meet agreed thresholds.

## Scorecard

| Measure | Definition | Pilot target |
|---|---|---|
| Median cycle time | Intake to reviewed output | Set after baseline; no invented target |
| Exact-source coverage | Released findings with reviewable supporting URL | Agree by source family |
| Golden-set accuracy | Correct supported result or correct abstention | Set before live pilot |
| Unresolved aging | Time until closure, escalation or documented stop | Service level set by owner |
| Human-review rate | Share requiring intervention and reason | Expected to decline only without accuracy loss |
| Cost per completed review | Integration, compute and reviewer time per accepted output | Compare with manual baseline |

## Public examples

- Lasting Ground: Python record-checking and report examples with fictional data.
- Evaluation tools: record checks, test cases and typed MCP interfaces.
- GroundTruth-Geo: 33 government-cited benchmark items across seven states with a deterministic grader and MCP interface.
- SquadBrain: an iOS app with selected public TypeScript examples and tests.

## Current product limits

Multi-town filtering is not generalized. State and country depth is uneven. Some rows identify an indexed official source rather than a record-level deep link. Lasting Ground has not yet had customers or received payments; this is a product-and-systems example, not a customer case study.
